INSURANCE CLAIMS & RISK ANALYSIS

Power BI Dashboard Analysis Report

1. Executive Summary

The dashboard summarizes insurance claim performance using overall claim value, claim frequency, average claim amount, vehicle usage, coverage zone, car year, and customer-related breakdowns. The visible headline figures are approximately **187.82M total claim amount**, **19K total claim frequency**, and **5.00K average claim amount**. These figures provide a high-level view of the claim portfolio, but should be validated against the underlying dataset and measure definitions before being used for business decisions.

2. Key Dashboard Indicators

Indicator	Displayed result	Interpretation
Total claim amount	187.82M	Represents the aggregate claim value displayed in the report.
Total claim frequency	19K	Shows the aggregated claim-frequency measure; confirm whether this is a count or a summed frequency field.
Average claim amount	5.00K	Provides a typical claim-size indicator based on the current measure.

3. Observations from the Visuals

Claim amount by car use: The donut chart indicates Private use contributes about 150.4M and Commercial use about 37.41M of the displayed claim total. Private use therefore represents the larger share in this view. Confirm that the chart uses the same claim-amount measure and filters as the headline KPI.

Average claim amount by coverage zone: The horizontal bars appear close in length, with displayed values around 5K across Urban, Suburban, Highly Rural, Highly Urban, and Rural zones. The current scale may make small differences difficult to see; add data labels or sort by value to make comparisons clearer.

Claim amount and household income by car year: The combo chart places claim amount and household income on different scales. The series show different patterns over time, but the relationship should not be described as causal. Consider checking missing or sparse early-year data and confirm that the vehicle-year field is the intended time dimension.

Claim frequency: The frequency gauge shows about 19K against a displayed maximum of 25K. A gauge is useful for progress against a target, but only if 25K is a meaningful business target. Otherwise, a KPI card with a trend chart may be more informative.

4. Business Interpretation

The visible breakdown suggests that Private vehicle usage accounts for most of the total claim amount in the current view. Coverage-zone averages appear broadly similar, so zone alone may not explain major differences in claim size. The dashboard can be used to explore how claims vary by vehicle year, coverage zone, and vehicle use; however, the visuals alone do not establish why the differences occur. More detailed analysis by policy exposure, customer count, vehicle age, and claim severity would be needed to explain risk drivers.

5. Recommendations

• Verify the definitions and units of all three KPI measures, especially whether Claim Freq is a count, a sum, or a precomputed frequency.

• Add a clear reporting period and note any page-level filters so readers know which records are included.

• Use consistent number formatting (for example, K/M units) and provide data labels for comparisons where readability permits.

• For the combo chart, label both axes clearly and use a legend that distinguishes claim amount from household income.

• If the gauge maximum is not a formal target, replace the gauge with a KPI card and a trend visual.

• Check data quality for null values, duplicate records, implausible vehicle years, and unusual claim amounts before drawing conclusions.

• Where possible, compare claim amount with customer or policy counts so larger totals are not mistaken for higher individual risk.

6. Limitations

This report is based on the uploaded Power BI report structure and the dashboard values/visuals visible in the provided screenshot. The underlying row-level data and complete filter context were not independently recalculated here. The values should therefore be treated as dashboard-reported figures, and the observations as descriptive rather than predictive or causal.

Prepared for dashboard documentation and presentation. Revalidate all totals directly in Power BI before submitting as a formal business report.
